Unit 5 : Session 4 : SLO 1 | Symbolic Programming Concepts

■ I. Questions & Answers

1. Symbolic computation is computation in which mathematical objects (variables, expressions, equations) are manipulated as exact symbols rather than approximate numbers, e.g. solving $x^2 - 1 = 0$ to get exactly $x = 1$ and $x = -1$.
2. Python library is SymPy is the standard Python library for symbolic computation (alternatives: SageMath; Octave/Mathematica outside Python).
3. Example of a symbolic equation is $\text{Eq}(x^2 + 2x + 1, 0)$, i.e. $x^2 + 2x + 1 = 0$; SymPy solves it exactly: `solve(x**2 + 2*x + 1, x)` returns `[-1]`.
